Sprint Reflection 5
Due: May 2, 2026

Goals

1. *Implement SQL Database for Users and Posts*

Met (y/n): y

I implemented an SQL database using SQLite3 and Sequelize. This was much more in depth than I had initially assumed it would be because the posts contain *a lot* of information. Consequently, I had to do a lot of refactoring. In addition to the post interaction functionality and, of course, user storage, this transition from in file storage to database storage required some new organization. I created a folder of frameworks for posts, replies, users, and likes that are all associated by relationships in an index file. These relationships are the basis for the entire functionality of the application. The app now functions the same way from a client's perspective, but the backend now operates from a database.

2. *Make Reply Usernames Clickable*

Met (y/n): y

This was done simply by adding the same two lines of code that allow this to happen for the posts themselves, a click event and changing the cursor from the standard cursor image used for text to a pointer type image.

3. *Show Time Stamp of Post in Post*

Met (y/n): y

Time stamps are already supported as items are pushed into a database, so using that was as simple as adding the "createdAt" element to the post assembly in the front end. I had to fiddle with the CSS to get it to look nice, but this was more tedious than difficult.

4. *Implement User Profile Picture*

Met (y/n): y

In order to do this, I had to make a small HTML addition to the register page that asks for a file upload to serve as a profile picture. I then added a folder to house user profile pictures and added logic that pulls the profile picture associated with the logged in user when a user logs in. This really should have been a lot easier than it was. I was chasing errors that I thought were file path issues, and they probably would've been, if it wasn't for the fact that I didn't update my nginx file to reflect the new folder that is housing the profile pictures. My Nginx was not properly serving the folder, and I was therefore getting silent failures. Once I corrected this, in order to finally get the profile pictures to load on user profile pages, I made to link the static "profile.png" placeholder to the frontend JS file which then was linked to a

new backend JS route that fetches the username and profile picture of any user. This is then reflected in the HTML profile page.

5. *Reverse Order of Posts*

Met (y/n): y

This was a simple addition of adding an “order” line in the end of the fetch posts function in the backend. This makes the posts load in descending order on the webpage, so the most recently made posts are at the top of the page.
